## Background

To gain a better understanding of the factors that predict recovery time from COVID-19 illness, a study was designed to combine three existing cohort studies that have been tracking participants for several years. The study collects recovery information through questionnaires and medical records, and leverages existing data on personal characteristics prior to the pandemic. The ultimate goal is to develop a prediction model for recovery time and identify important risk factors for long recovery time.

#### Data

The dataset in recovery.RData includes data from 3000 participants.

Here is a description of each variable:

- ID (id): Participant ID
- Gender (gender): 1 = Male, 0 = Female
- Race/ethnicity (race): 1 = White, 2 = Asian, 3 = Black, 4 = Hispanic
- Smoking (smoking): Smoking status; 0 = Never smoked, 1 = Former smoker, 2 = Current smoker
- Height (height): Height (in centimeters)
- Weight (weight): Weight (in kilograms)
- BMI (bmi): Body Mass Index; BMI = weight (in kilograms) / height (in meters) squared
- Hypertension (hypertension): 0 = No, 1 = Yes
- Diabetes (diabetes): 0 = No, 1 = Yes
- Systolic blood pressure (SBP): Systolic blood pressure (in mm/Hg)
- LDL cholesterol (LDL): LDL (low-density lipoprotein) cholesterol (in mg/dL)
- Vaccination status at the time of infection (vaccine): 0 = Not vaccinated, 1 = Vaccinated
- Severity of COVID-19 infection (severity): 0 = Not severe, 1= Severe
- Study (study): The study (A/B) that the participant belongs to
- Time to recovery (recovery\_time): Time from COVID-19 infection to recovery in days

#### **Data Preparation**

Partition the dataset into two parts: a matrix of predictors and a vector of response.

```
load("data/recovery.RData")

dat = dat |>
    select(-id)

# matrix of predictors & vector of response for data set exploration
x.dat = model.matrix(recovery_time ~., dat)[, -1]
y.dat = dat$recovery_time
```

## Exploratory analysis and data visualization

```
dat_ds <- dat |>

ds = t1kable(descriptive_table)
```

There are no missing values in the dataset. The distribution of the demographic variables age, gender, race are about the same between treatment groups. Mean height, weight, BMI, SBP and LDL variables are also similarly distributed between groups. There are more people who are vaccinated than not vaccinated in study group A and B, and also there are more participants who are reported to have not severe COVID-19 infections. recovery\_time mean and SD is higher for Study B. There is also a larger interval range.

#### Response Variable Exploration

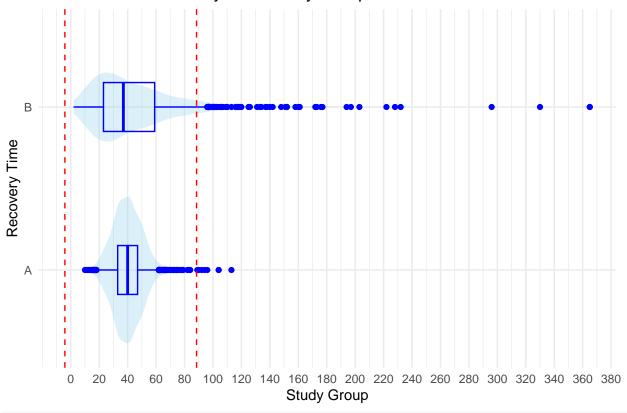

```
# Calculate mean and standard deviation
mean_value = mean(dat$recovery_time)
sd_value = sd(dat$recovery_time)
```

    labels = seq(0, 400, by = 20)
  )
print(boxplot_recovery)
```

## Distribution of Recovery Time Study Group

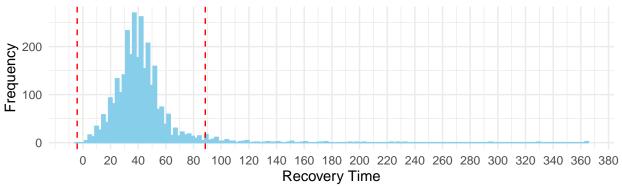

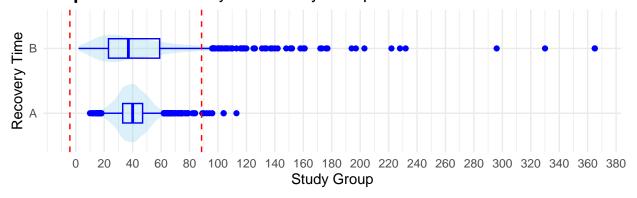

```
combined_recovery =
   plot_grid(histogram_recovery, boxplot_recovery, labels = c("Histogram", "Boxplot"), ncol = 1)
# Show the combined plot
print(combined_recovery)
```

Feature Plot

## HDistrologram of Days to Recovery post COVID-19 Infection with Outliers Hig

## Bistpibation of Recovery Time Study Group

Using a cut-off based on the standard deviation  $\pm$  2 times the mean, there are a total 92 outliers (approximately 3% of the observations). These outliers will be excluded from future analysis. Specifically, among the outliers, 84 belong to the study group B population.

```
# removing recovery_time outliers
dat2 =
  dat |>
  filter(recovery_time >= outlier_low & recovery_time <= outlier_high)

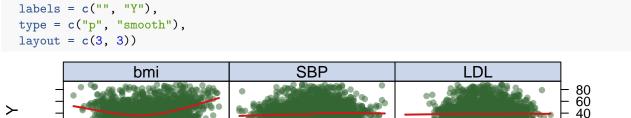

x.dat2 = model.matrix(recovery_time ~., dat2)[, -1]
y.dat2 = dat2$recovery_time</pre>
```

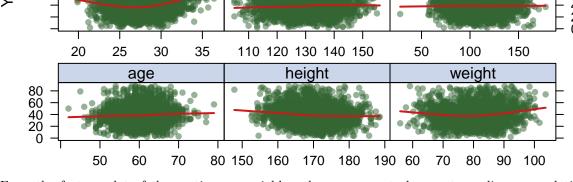

#### Feature Plot

```
theme1 <- trellis.par.get()
theme1$plot.symbol$col <- rgb(.2, .4, .2, .5)
theme1$plot.symbol$pch <- 16
theme1$plot.line$col <- rgb(.8, .1, .1, 1)
theme1$plot.line$lwd <- 2
theme1$strip.background$col <- rgb(.0, .2, .6, .2)
trellis.par.set(theme1)

featurePlot(
    x.dat2[, -c(2, 3, 4, 5, 6, 7, 11, 12, 15, 16, 17)],
    y.dat2,
    plot = "scatter",</pre>
```

Correlation Matrix 12

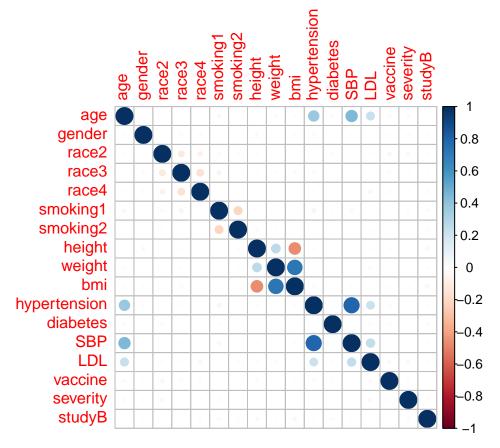

From the feature plot of the continuous variables, there appears to be no strong linear correlations with our response variable recovery\_time. bmi and weight however show a potential non-linear relationship. A GAM or MARS model may be best (Do we want to do a transformation?)

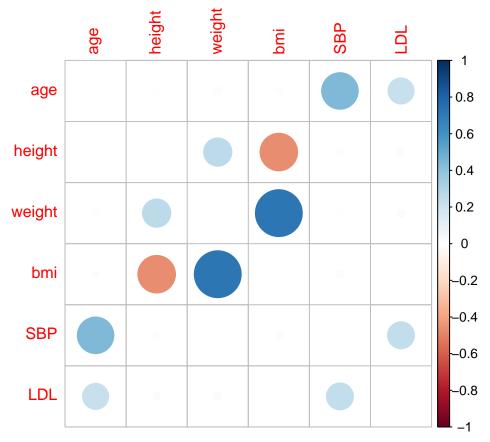

#### **Correlation Matrix**

Correlation Matrix 13

The correlation matrix between predictors indicates multicollinearity between bmi and weight, sbp and hypertension, and potentially bmi and height.

## Model Training in caret

#### Test and Train Data Preparation

```
set.seed(2)
# create a random split of 80% training and 20% test data
data_split <- initial_split(data = dat2, prop = 0.8)</pre>
# partitioned datasets
training_data = training(data_split)
testing_data = testing(data_split)
# training data
x <- model.matrix(recovery_time ~ ., training_data)[, -1] # matrix of predictors
head(x)
     age gender race2 race3 race4 smoking1 smoking2 height weight bmi
